Briefly

Matsui's Linear Cryptanalysis is based on the distribution of

 $x_1 \oplus \ldots \oplus x_s \oplus y_1 \oplus \ldots \oplus y_t$

where $X = x_1, \ldots, x_s$ some plain-text bits and $Y = y_1, \ldots, y_t$ some cipher-text bits in Algorithm1

- In Algorithm2 the bits X are inputs to the second round, and Y to the last round
- ► Starting point in our work: method for computing joint distribution of (X, Y) = (x₁,...,x_s, y₁,...,y_t)
- ► The distributions (both Matsui's and our's) are approximate
- They depend on small sets of the cipher key-bits or linear combinations
- Algorithm2-like cryptanalysis is then applied

- Matsui's Algorithm2 and LLR statistic
- New Statistic Construction
- Optimisation Problem and Search Algorithm
- Implementation for 16-round DES
- Multidimensional Distributions in Feistel Ciphers

Conclusions

- Matsui's Algorithm2 and LLR statistic
- > >

Round Cipher Cryptanalysis with Algorithm2

▶ ▲ 돌 ▶ 돌 ∽ � �

Logarithmic Likelihood Ratio(LLR) Statistic

- To distinguish two distributions with densities P(x), Q(x)
- By independent observations $\nu_1, ..., \nu_n$
- Most powerful test(Neyman-Pearson lemma):
- Accept P(x) if

$$\sum_{i=1}^n \ln rac{P(
u_i)}{Q(
u_i)} > threshold$$

Left hand side function is called LLR statistic

Algorithm2 Cryptanalisis with LLR statistic

- Distribution of (X, Y) depends on key-bits key
- Observation on (X, Y) depends on key-bits Key
- ▶ LLR statistic depends on *key* ∪ *Key*
- ▶ Distinguish correct and incorrect key ∪ Key with LLR statistic

- ▶ by computing 2^{|key∪Key|} values of LLR
- For large (X, Y) the number of the key-bits involved |key ∪ Key| may be too large
- Not efficient

New Statistic

- ▶ Instead of 2^{|key∪Key|} computations of LLR-values
- Our work: << 2^{|key∪Key|}(≈ 10³ times faster in DES)

- By using a new statistic
- Which reflects the structure of the round function
- That has a price to pay, but trade-off is positive

- New Statistic Construction

►

- .

- (ロ) (母) (言) (言) 言 の(の)

LLRs for Projections

- $(h_1, .., h_m)$ some subvectors (projections) of (X, Y) such that
- ► Distribution and Observation for h_i depend on a lower number of the key-bits key_i ∪ Key_i
- LLR_i is a LLR-statistic for h_i
- ▶ Vector (*LLR*₁,..,*LLR*_m) asymptotically distributed
- *m*-variate $N(n\mu, nC)$ if key \cup Key is correct
- Close to $N(-n\mu, nC)$ if $key \cup Key$ is incorrect
- Mean vector μ , covariance matrix C, number of plain-texts n

LLR for Two Normal Distributions

- LLR statistic S to distinguish two normal distributions $N(n\mu, nC)$ and $N(-n\mu, nC)$
- S degenerates to linear:

•
$$S(\text{key} \cup \text{Key}, \nu) = \sum_{i=1}^{m} S_i(\text{key}_i \cup \text{Key}_i, \nu_i),$$

- where $S_i = \omega_i LLR_i$ weighted LLR statistic for h_i
- ν observation on (X, Y) and ν_i observation on h_i
- S is separable
- For polynomial distributions the theory of separable statistics was developed by lvchenko, Medvedev,... in 1970-s

Distribution

▶ S distributed 1-variate N(u, u) if key \cup Key correct

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

- Close to N(-u, u) if incorrect
- for an explicit positive u

Cryptanalysis

▶ Find key ∪ Key s.t.

 $S(key \cup Key, \nu) > threshold$

- ▶ without brute forcing key ∪ Key
- Can be done as
- $S(key \cup Key, \nu) = \sum_{i=1}^{m} S_i(key_i \cup Key_i, \nu_i)$
- ▶ and $|key_i \cup Key_i|$ is much smaller than $|key \cup Key|$
- ▶ $|key \cup Key| = 54$ and $|key_i \cup Key_i| \approx 20$ in DES
- By solving efficiently an optimisation problem with a Search Algorithm

Optimisation Problem and Search Algorithm

(ロ)、(型)、(E)、(E)、 E) の(の)

- •

Optimisation Problem Example

S_1	0.1	0.2	0.3	0.1	
$x_1 \oplus x_3$	0	0	1	1	
<i>x</i> ₂	0	1	0	1	
	_		1		
S_2		0.5	0.1		
$x_1 \oplus x_2$		0	1		
S_3	0.4	0.5	0.7	0.1	
<i>x</i> ₁	0	0	1	1	
$x_2 \oplus x_3$	0	1	0	1	

find binary x_1, x_2, x_3 s.t.

 $S(x_1, x_2, x_3) = S_1(x_1 \oplus x_3, x_2) + S_2(x_1 \oplus x_2) + S_3(x_1, x_2 \oplus x_3) > 1.3$

Threshold is 1.3, solution 111

Search Tree

- One walks over a search tree and checks if the inequality $S_1(x_1 \oplus x_3, x_2) + S_2(x_1 \oplus x_2) + S_3(x_1, x_2 \oplus x_3) > 1.3$
- feasible under current fixation
- Cut if not feasible. Continue if feasible
- One is to check 6 linear inequalities. Brute force takes 8
- Same way one solves

$$S(key \cup Key, \nu) = \sum_{i=1}^{m} S_i(key_i \cup Key_i, \nu_i) >$$
threshold

Success Probability Number of $(key \cup Key)$ -candidates

 Search tree output is (key U Key)-candidates for the final brute force

- The distribution of $S(key \cup Key, \nu)$ is known
- So one can compute success probability and
- ► The number of wrong solutions, that is (key ∪ Key)-candidates

- •
- Implementation for 16-round DES

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

►

Two 14-bit vectors

•
$$DES_{K}(X_{0}, X_{1}) = (X_{17}, X_{16})$$

Matsui's best linear approximation

 X_{2} {24, 18, 7} \oplus X_{15} {15} \oplus X_{16} {24, 18, 7, 29}

We use two 14-bit vectors

 $X_2[24, 18, 7, 29], X_{15}[16, 15, ..., 11], X_{16}[24, 18, 7, 29]$ $X_1[24, 18, 7, 29], X_2[16, 15, ..., 11], X_{15}[24, 18, 7, 29]$

- Considered independent as they incorporate different bits
- Computing their distributions took a few seconds

Projections

28 projections

 $X_2[24, 18, 7, 29], X_{15}[i, j], X_{16}[24, 18, 7, 29]$ $X_1[24, 18, 7, 29], X_2[i, j], X_{15}[24, 18, 7, 29]$

- ▶ For each projection *LLR* depends on (\leq 21) key-bits
- 54 key-bits overall
- Two separable statistics for two independent bunches of the projections
- ► Search Algorithm combines (≤ 21)-bit values to find 54-bit candidates

Those candidates are brute forced

One Particular Projection

▶ projection *h*₁:

 $X_2[24, 18, 7, 29], X_{15}[16, 15], X_{16}[24, 18, 7, 29]$

• $key_1 \cup Key_1$ incorporates 20 unknowns

 $\begin{aligned} & x_{63}, x_{61}, x_{60}, x_{53}, x_{46}, x_{42}, x_{39}, x_{36}, x_{31}, \\ & x_{30}, x_{27}, x_{26}, x_{25}, x_{22}, x_{21}, x_{12}, x_{10}, x_{7}, x_{5}, \\ & x_{57} + x_{51} + x_{50} + x_{19} + x_{18} + x_{15} + x_{14} \end{aligned}$

 x_i key-bits of 56-bit DES key

- 2^{20} values of $S_1 = \omega_1 LLR_1$
- Similar for other 27 projections

Key-variables Order for the Search Tree

▶ One needs *key* ∪ *Key* ordered to run a tree search

▶ x_2 appears in 14(maximal number) of $key_i \cup Key_i$, etc

X2, X19, X60, X34, X10, X17, X59, X36, X42, X27, X25,
X52, X11, X33, X51, X9, X23, X28, X5, X55, X46, X22,
X62, X15, X37, X47, X7, X54, X39, X31, X29, X20, X61,
X63, X30, X38, X26, X50, X1, X57, X18, X14, X35, X44,

*x*₃, *x*₂₁, *x*₄₁, *x*₁₃, *x*₄, *x*₄₅, *x*₅₃, *x*₆, *x*₁₂, *x*₄₃

Search Tree Algorithm Run

- We fixe desirable success rate 0.83
- solve equation n = |keys to brute force| in n
- got $n = 2^{41.8}$

- The number of tree nodes is shown, log₂ scale
- $|(key \cup Key)$ -candidates $| = 2^{39.8}$, |keys to brute force $| = 2^{41.8}$
- ► Number of nodes is 2^{45.5} << 2⁵⁴. Constructing the nodes is faster (in bit operations) than final brute force
- Improves Matsui's result on $DES(n = 2^{43}, 0.85)$

- •

- Multidimensional Distributions in Feistel Ciphers

r-Round DES

• $\mathsf{DES}_{\mathcal{K}}(X) = Y$, where X random, \mathcal{E} any event

- We want to compute $Pr(\mathcal{E})$ in *r*-round DES. Let's formalise
- ► X₀, X₁,..., X_{r+1} random independently generated 32-bit blocks. Event C defines DES:

$$X_{i-1} \oplus X_{i+1} = F_i(X_i, K_i), \quad i = 1, \ldots, r$$

• K_1, \ldots, K_r fixed round keys. We need

$$\Pr(\mathcal{E}|\mathcal{C}) = \frac{\Pr(\mathcal{E}\mathcal{C})}{\Pr(\mathcal{C})} = 2^{32r}\Pr(\mathcal{E}\mathcal{C})$$

infeasible as C depends on all key-bits

$\mathsf{Relax}\ \mathcal{C}$

• One chooses a larger event C_{α} (that is C implies C_{α})

$$X_{i-1}[\alpha_i] \oplus X_{i+1}[\alpha_i] = F_i(X_i, K_i)[\alpha_i], \quad i = 1, \dots, r$$

• where $\alpha = (\alpha_1, \dots, \alpha_r)$. Then

$$\mathbf{Pr}(\mathcal{C}_{\alpha}) = 2^{-\sum_{i=1}^r |\alpha_i|}$$

Let's accept

$$\mathsf{Pr}(\mathcal{E}|\mathcal{C}) \approx \mathsf{Pr}(\mathcal{E}|\mathcal{C}_{\alpha}) = \frac{\mathsf{Pr}(\mathcal{E}\mathcal{C}_{\alpha})}{\mathsf{Pr}(\mathcal{C}_{\alpha})} = 2^{\sum_{i=1}^{r} |\alpha_{i}|} \mathsf{Pr}(\mathcal{E}\mathcal{C}_{\alpha})$$

 C_α depends on a lower number of the key-bits. Now feasible and may be computed exactly

Regular Trails

To compute the distribution of

$$Z = X_0[\alpha_1], X_1[\alpha_2 \cup \beta_1], X_r[\alpha_{r-1} \cup \beta_r], X_{r+1}[\alpha_r]$$

• One chooses event C_{α} , where $\alpha = (\alpha_1, \dots, \alpha_r)$, and the trail

$$X_i[\beta_i], F_i[\alpha_i], \quad i=1,\ldots,r$$

The trail is called regular if

$$\gamma_i \cap (\alpha_{i-1} \cup \alpha_{i+1}) \subseteq \beta_i \subseteq \gamma_i, \quad i = 1, \dots, r$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

where $X_i[\gamma_i]$ input bits relevant to $F_i[\alpha_i]$

For a regular trail Pr(Z = A|C_α) is computed with a convolution-type formula, only depends on α_i

Convolution Formula

$$\blacktriangleright Z = X_0[\alpha_1], X_1[\alpha_2 \cup \beta_1], X_r[\alpha_{r-1} \cup \beta_r], X_{r+1}[\alpha_r]$$

• Then $\mathbf{Pr}(Z = A_0, A_1, A_r, A_{r+1} | \mathcal{C}_{\alpha}) =$

$$\frac{2^{\sum_{i=2}^{r-1} |\alpha_i|}}{2^{\sum_{i=1}^{r} |(\alpha_{i-1}\cup\alpha_{i+1})\setminus\beta_i|}} \sum_{A_2,\dots,A_{r-1}} \prod_{i=1}^{r} \mathbf{q}_i (A_i[\beta_i], (A_{i-1}\oplus A_{i+1})[\alpha_i], k_i)$$

probability distribution on round sub-vectors

$$\mathbf{q}_{\mathbf{i}}(b, a, k) = \mathbf{Pr}(X_{i}[\beta_{i}] = b, F_{i}[\alpha_{i}] = a|K_{i}[\delta_{i}] = k)$$

- K_i[δ_i] key-bits relevant to F_i[α_i]
- May be computed iteratively by splitting encryption into two parts. A few seconds for 14-round DES

- ►

- Conclusions

Conclusions

- Method of computing joint distribution of encryption internal bites X, Y(for Feistel ciphers) is found
- Conventional LLR statistic is inefficient for large X, Y. New statistic reflects round function structure
- We computed its distribution and able to predict success probability and the size of the final brute force
- Efficient Search Algorithm to find key-candidates which fall into critical region is presented

- Got an improvement over Matsui's results in DES (at least in bit operations)
- Predicted correctly success probability(8-round DES) and the number of final key-candidates(16-round DES)
- Search Algorithm is 10³ times faster than brute forcing all key-bits which affect the statistic
